- Theoretical solid state physics
  - Modeling materials with crystal structure

 $N \sim 10^{23}$ 

$$\hat{H} = -\frac{1}{2} \sum_{i}^{N_{e}} \nabla_{i}^{2} - \sum_{i}^{N_{e}} \sum_{I}^{N_{n}} \frac{Z_{I}}{|\vec{r_{i}} - \vec{R_{I}}|} + \frac{1}{2} \sum_{i}^{N_{e}} \sum_{j \neq i}^{N_{e}} \frac{1}{|\vec{r_{i}} - \vec{r_{j}}|} + \frac{1}{2} \sum_{I}^{N_{n}} \sum_{J \neq I}^{N_{n}} \frac{Z_{I}Z_{J}}{|\vec{R_{I}} - \vec{R_{J}}|}$$

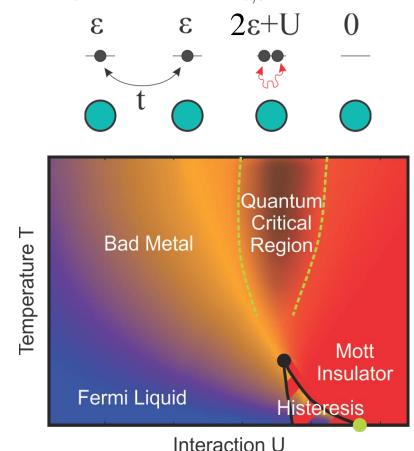

- Weakly correlated materials
  - Conventional metals
  - Band-insulators
  - Semi-conductors
  - Described well by effective single-particle theories (e.g. DFT+LDA)
- Strongly correlated materials
  - High Tc Superconductors (Cuprates and Fe based)
  - Numerous Transition metal oxides exhibiting metalinsulator transition
  - Rare-earth and actinide intermetallics
  - Kapa-organics
  - Still lack theories with predictive power
- To understand emergent phenomena like macropscopic quantum phases of matter, one must tackle a true many-body QM problem

Hubbard Model

$$\hat{H} = -t \sum_{\langle \vec{i}, \vec{j} \rangle, \sigma} \left( c^{\dagger}_{\vec{i}, \sigma} c_{\vec{j}, \sigma} + \text{h.c.} \right) + U \sum_{\vec{i}} \hat{n}_{\vec{i}, \uparrow} \hat{n}_{\vec{i}, \downarrow} - \varepsilon \sum_{\vec{i}, \sigma} \hat{n}_{\vec{i}, \sigma}$$

- A very simplified model:
  - No details of atomic structure
  - No lattice dynamics (phonons)
  - No long-range interactions
  - No disorder

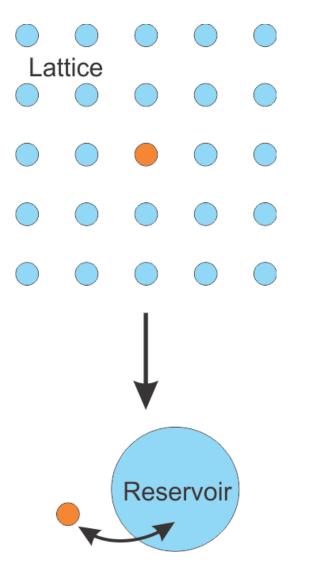

- Exactly soluble only in
  - d=1
  - $d=\infty$  (Dynamical Mean Field Theory)

H. Terletska, J. Vucicevic, D. Tanaskovic, V. Dobrosavljevic Phys. Rev. Lett. 107, 026401 (2011)

### • DMFT solution of the Hubbard Model

A. Georges, Rev. Mod. Phys., Vol. 68, No. 1, (1996)

#### IT'S A MEAN-FIELD THEORY

The approach is simillar to the Weiss-Curie mean-field theory of magnetism

• The environment of a site is replaced by an effective bath of electronic states described by the self-consistently determined Hybridization function

#### **IT IS DYNAMICAL**

The effective fermionic field is frequency dependent so that the temporal fluctuations are fully taken into account

• Electrons are allowed to hop in and out from the bath

### • DMFT solution of Hubbard Model

DMFT method assumes that the self-energy is purely local

In finite dimensions, it neglects spatial fluctuations

Exact only in infinite dimensions

Works particurarly well in cases when self-energy locality is a reasonable approximation

- Lattice has a large coordination number
- Long range order is geometrically frustrated
- Temperature is high as compared to the Fermi liquid coherence temperature
- Away from near vicinity of critical points

## Numerical solution: The DMFT Loop

Step 0:

Pick an arbitrary Hybridazation fucntion

Step 1: Solve the Single Impurity Anderson Model (SIAM)

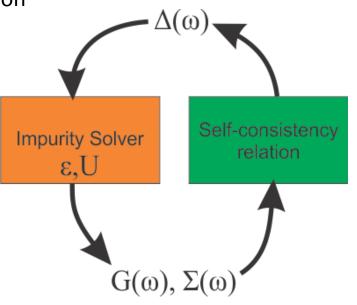

$$\hat{H} = -\sum_{\vec{k},\sigma} \varepsilon_{\vec{k}} \left( c^{\dagger}_{\vec{k},\sigma} c_{\vec{k},\sigma} + \text{h.c.} \right) - V \sum_{\vec{k},\sigma} \left( f^{\dagger}_{\sigma} c_{\vec{k},\sigma} + \text{h.c.} \right) - \varepsilon_f \sum_{\sigma} \left( f^{\dagger}_{\sigma} f_{\sigma} + \text{h.c.} \right) + U f^{\dagger}_{\uparrow} f^{\dagger}_{\downarrow} f_{\uparrow} f_{\downarrow}$$

Step 2:

Use the solution of SIAM (Green's function and Self-energy) to Calculate a Hybridization function using the Self consistency relation

$$\Delta(\omega) = \omega + \mu - \Sigma(\omega) - G^{-1}(\omega)$$

Step 3: GOTO Step 1

## Single Impurity Anderson Model solvers

- Exact
  - CTQMC (Continuous Time Quantum Monte Carlo)
    - N.V. Prokof'ev, JETP Lett. 64, 911 (1996), P. Werner, Phys. Rev. Lett. 97, 076405 (2006),
    - Noisy

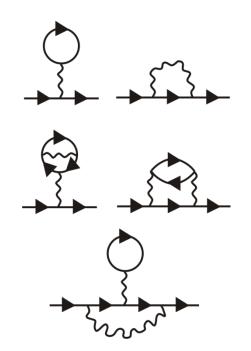

K. Haule, Phys. Rev. B 75, 155113 (2007)

- Computationally intensive
- Formulated on the imaginary axis
- ED (Exact Diagonalization)
  - Unfeasible unless Hybridization bath is approxiated with only a small number of orbitals
- NRG (Numerical Renormalization Group)
  - Works well only at zero termperature
- Approximate
  - NCA (Non-crossing approximation)
  - SB (Slave boson)
  - SOP (Second order perturbative solution)

 $G(i\omega_n) \rightarrow G(\omega) \rightarrow \rho(\omega)$ 

Not an easy task!

- The DMFT with SOP impurity solver a.k.a. The iterative perturbation theory (IPT)
  - Approximate
    - Takes into account the Feynman diagrams of only up to the second order
  - Computationally not very demanding
  - Can be formulated on both real and imaginary axes
  - In good qualitative and even quantitative agreement with CTQMC

H.Kajueter, Phys. Rev. Lett. 77, 131–134 (1996) M. Potthoff, Phys. Rev. B 55, 16132–16142 (1997) • Disordered systems

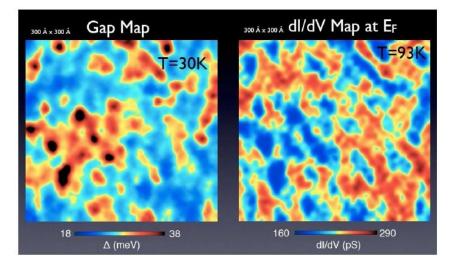

Crystal lattices are usually not perfect...

- Structural defects

   Interstitial atoms
   Vacancies
   Deviations from the perfect
   translational symmetry
- Impurities

... but highly doped systems are usually very disordered, with many dopants distributed randomly across the lattice.

DMFT for disordered systems: each lattice site has different properties and a different environment and must be treated as an independent impurity problem!

STM images of the spatial distribution of the superconducting gap and normal phase conductivity of the doped Bi<sub>2</sub>Sr<sub>2</sub>CaCu<sub>2</sub>O<sub>8+x</sub>

The efficiency of IPT is of great importance.

$$G_{0}(\omega) = \frac{1}{\omega + \mu_{0} - \Delta(\omega)}$$

$$n_{d} = -\frac{1}{\pi} \int G_{0}(\omega) f(\omega) d\omega$$

$$A^{\pm}(\omega) = -\frac{1}{\pi} G_{0}''(\omega) f(\pm \omega)$$

$$P_{1}(\omega) = \pi \int A^{-}(\omega') A^{+}(\omega' - \omega) d\omega'$$

$$P_{2}(\omega) = \pi \int A^{+}(\omega') A^{-}(\omega' - \omega) d\omega'$$

$$Im\Sigma^{(2)}(\omega) = -U^{2} \int \left[ A^{+}(\omega - \omega') P_{2}(\omega') \right] d\omega'$$

$$Re\Sigma^{(2)}(\omega) = -\frac{1}{\pi} \int \frac{Im\Sigma^{(2)}(\omega')}{\omega - \omega'} d\omega'$$

$$B_{0} = \epsilon_{d} - \frac{1}{\pi} \frac{1m\Sigma^{(2)}(\omega')}{\omega - \omega'} d\omega'$$

$$B_{0} = \epsilon_{d} - \frac{1}{\pi} \frac{1m\Sigma^{(2)}(\omega)}{m(1 - n_{d})U^{2}} d\omega'$$

$$b = \frac{(1 - 2n_{d})U - \mu + (\mu_{0} + \epsilon_{d} + Un_{d}) - B + B_{0}}{n_{d}(1 - n_{d})U^{2}}$$

$$\Sigma(\omega) = Un_{d} + \frac{\Sigma^{(2)}(\omega)}{1 - b\Sigma^{(2)}(\omega)}$$

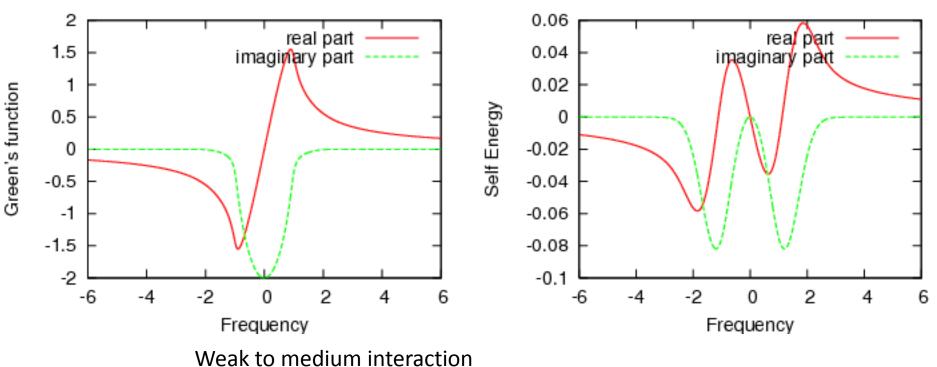

$$G(\omega) = \int \frac{\rho(\varepsilon) d\varepsilon}{\omega + \mu - \varepsilon - \Sigma(\omega)}$$

$$\Sigma(\omega), G(\omega)$$

• General numerical issues

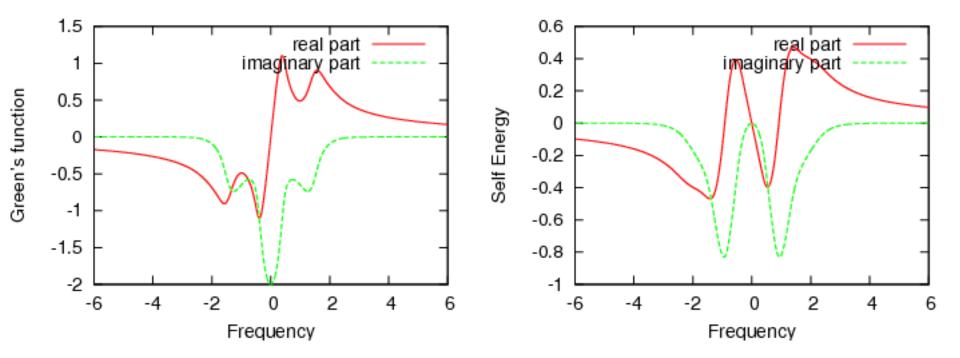

Function discretization grid  $G(\omega) \longrightarrow G(\omega_i)$ 

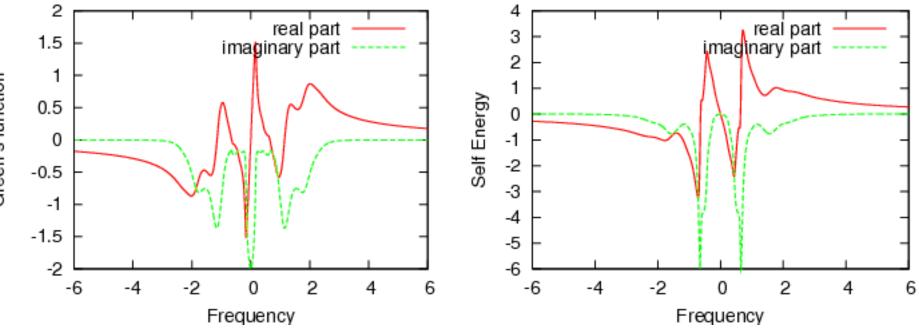

A uniform but dense grid can be good enough...

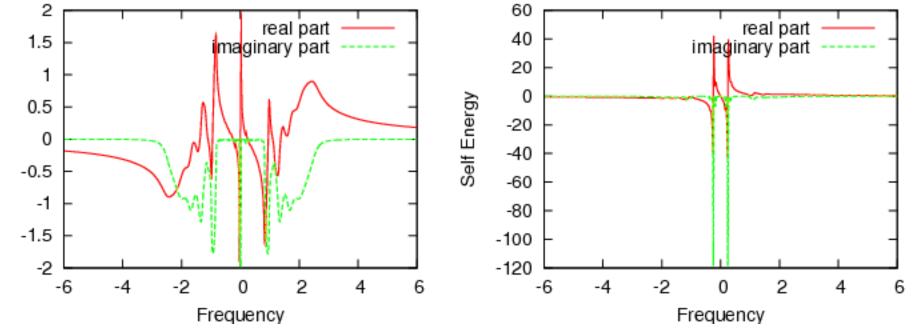

Relatively featureless Green's function and self-energy

Metallic solution

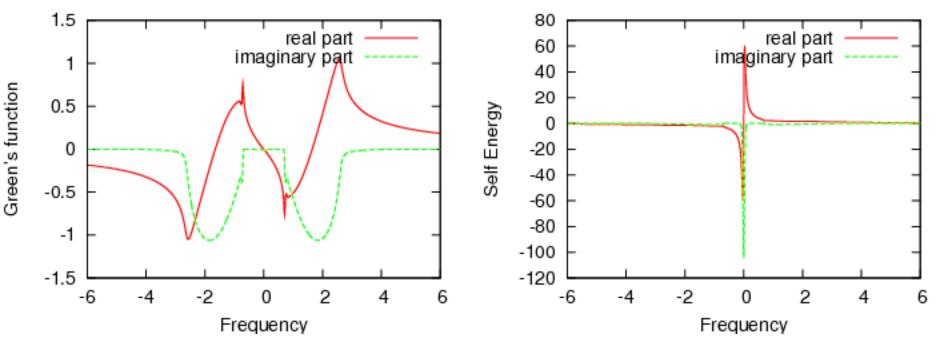

• General numerical issues

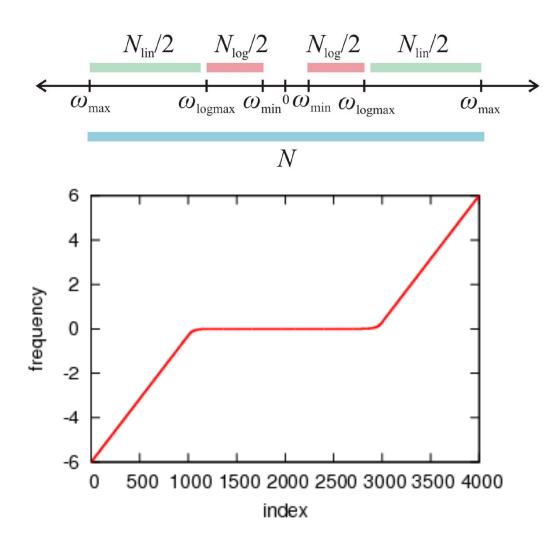

Function discretization grid  $G(\omega) \longrightarrow G(\omega_i)$ 

... but is not good enough for a Mott-insulator

Very sharp delta-like peaks in Self-energy at zero frequency Have to be resolved with high precision General numerical issues

Function discretization grid

A combination of logarithmic and uniform grids

The majority of points is located around zero frequency

General numerical issues

### Integration

Trapezoidal integration is sufficient

Using adaptive grids for integrands with features away from zero frequency could in principle increase precision and efficiency

### Integration of divergent integrands

$$\begin{split} G(\omega) &= \int \frac{\rho(\varepsilon)d\varepsilon}{\omega + \mu - \varepsilon - \Sigma(\omega)} & \text{Straight-forward integration fails} \\ &= \int \frac{\rho(\varepsilon)d\varepsilon}{\omega + \mu - \varepsilon - \Sigma(\omega) + i\eta} & \text{Easy solution degrades the result} \\ &= \int d\varepsilon \frac{\rho(\varepsilon) - \rho(\omega + \mu - \Sigma(\omega))}{\omega + \mu - \varepsilon - \Sigma(\omega)} + \rho(\omega + \mu - \Sigma(\omega)) \int \frac{d\varepsilon}{\omega + \mu - \varepsilon - \Sigma(\omega)} \\ &= \int d\varepsilon \frac{\rho(\varepsilon) - \rho(\omega + \mu - \Sigma(\omega))}{\omega + \mu - \varepsilon - \Sigma(\omega)} + \rho(\omega + \mu - \Sigma(\omega)) \log \frac{\omega + \mu - \Sigma(\omega) + \omega_{max}}{\omega + \mu - \Sigma(\omega) - \omega_{max}} \end{split}$$

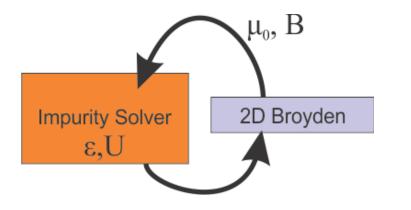

Smart solution works well!

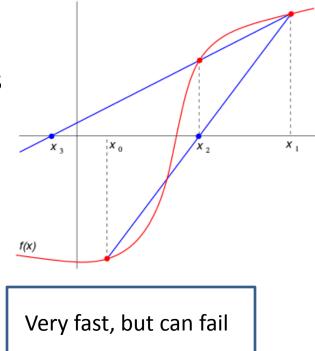

• Optimization

### Solving systems of non-linear equations

Broyden solver – generalization of secant method in 1D

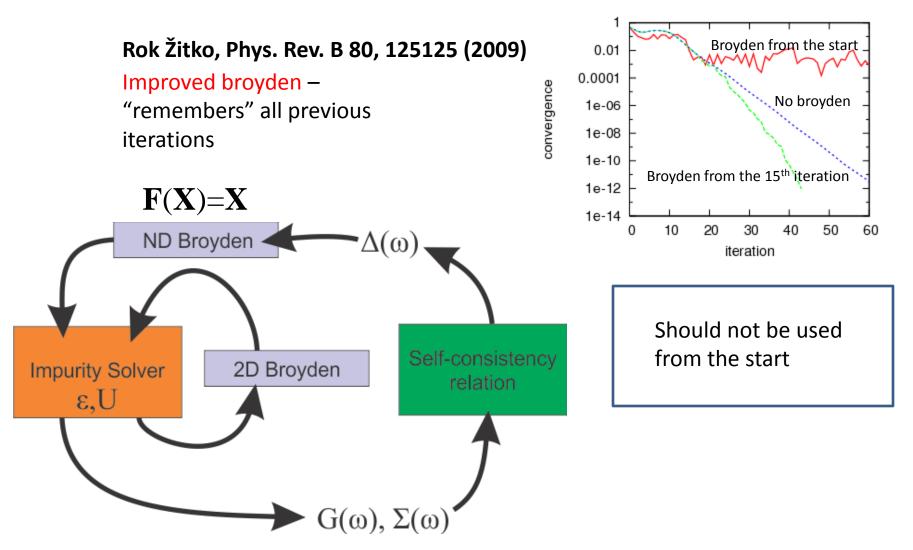

In some cases, solving SIAM = solving a system of 2 equations (2 parameters need to be fixed selfconsistently)

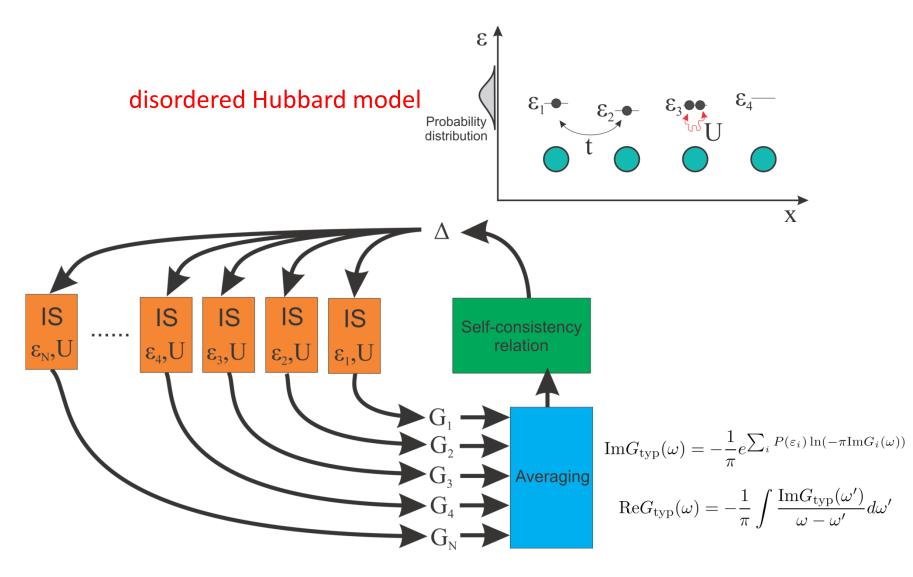

When Broyden fails, the procedure has to be restarted with another initial guess • Optimization

Speeding up the convergence of the DMFT loop

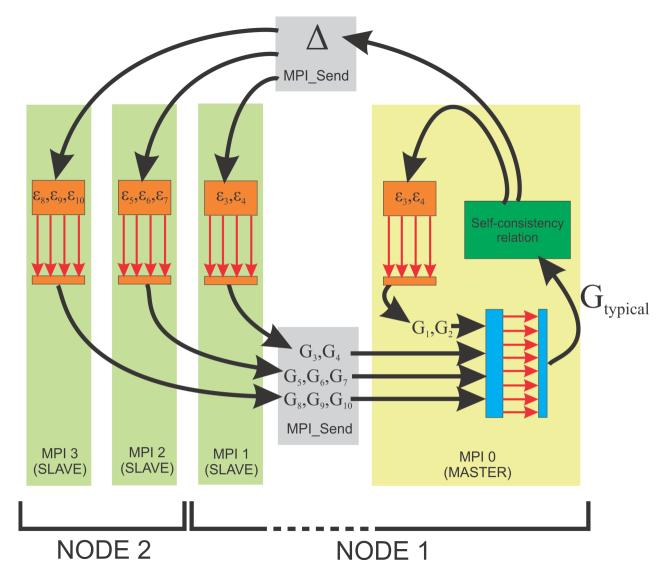

• Application in Typical medium theory (TMT)

V. Dobrosavljević, Europhys. Lett. 62 76, (2003)

• Hybrid implementation of TMT

- This Example:
- 4 MPI processes
- 4 OpenMP threads per MPI process
- solving 10 impurities

Hybrid implementation of TMT

Tested on:

2 computational nodes of 8 cores (Intel Xeon E5405 @ 2.00GHz) interconnected by Infiniband

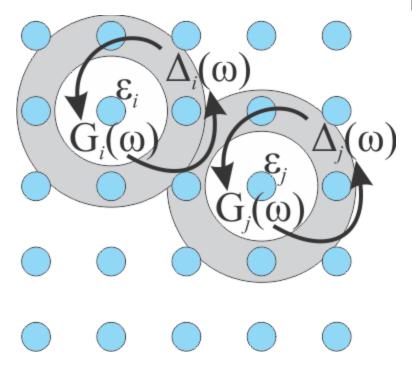

- Intel compiler (icpc)
- OpenMPI + Intel OpenMP
- This Example:
- 41 iterations for convergence
- U=0.1, T=0.1, W=0.3
- solving 32 impurities
- 2000 points in freq grid

Number of MPI processes	Number of OpenMP threads per MPI process	Execution time [min:sec]
1	1	31:01
1	2	15:46
1	4	07:58
1	8	04:06
16	1	02:20
8	2	02:10
4	4	02:08
2	8	02:07

## • Statistical (Inhomogeneous) DMFT

Deals with disorder in a more detailed way : every lattice site is coupled to a different bath determined by green's functions of surrounding lattice sites

A step forward from the mean-field philosophy!

Finite dimensions and finite samples

Energies are randomized – many realizations are needed to get statistical averages

> Large matrix inversion needs to be done in every iteration – MKL library routine does the job

Massive computation - would take months with CTQMC
